Abstract

Background and Aim: Estimating the maximal aerobic capacity in humans can be used to establish the proportionality between the worker and work physiology. This study was conducted to determine VO₂-max and its associated factors among male workers of industrial sector of Sanandaj city.

Method: To conduct this study, 200 healthy and non-smoking male workers were randomly selected. Maximal aerobic capacity (VO₂-max) was measured by Tuxworth & Shahnnavaz method. T test and one way ANOVA test were used to examine the relationship between qualitative variables and VO₂max mean and quantitative variables and VO₂-max mean, respectively. The stepwise multiple linear regression analysis was used to build the best model.

Results: According to results, workers' maximal aerobic capacity mean was estimated to be 2.92±0/34 Lit/M. The results showed that there was association between VO₂-max and weight and marital status while no association was found between VO₂-max and height, BMI, age, education level, shift working, job satisfaction, exercise per week and fatigue.

Conclusion: Weight and marital status are the factors affecting the maximal aerobic capacity.

Keywords: Maximum aerobic capacity, physiologically fitting, Physical work capacity, Tuxworth & Shahnnavaz protocol.
